  • Source – Path – Receiver
  • Sound waves
  • Ear
    • Anatomy and Function
• Hearing loss (DEMO)
  • Causes, Prevention, Treatment
  • Hearing loss in the Military
• Perception of sound
  • Everyone perceives sound differently – Its Subjective!
  • Equal Loudness (DEMO)
  • Frequency Filtering (DEMO)
  • Perceived Relative Sound Level (DEMO)
• Masking (DEMO)
The source-path-receiver paradigm is very important for noise control engineering measurements.

- **Source**
  - Can be a system, sub-system, or component
  - Has a power level and a direction

- **Path**
  - Any path the acoustic waves take between source and receiver
  - Can be multiple paths
  - Can be fluid-borne, structure-borne, or combination of both
  - Consist of magnitude and direction

- **Receiver**
  - Anything that senses the acoustic wave
    - Ear
    - Structure
    - Sensor (microphone)
Sound is a pressure wave in air
Equation of pressure wave

\[ y(t) = A \sin(\omega t + \varphi) \]

- \( A \): amplitude of the pressure wave (Pa)
- \( \omega \): angular frequency (rad/s) = 2\(\pi\)\(f\) (Hz)
- \( \varphi \): phase shift (rad). Represents how much time delay the waveform has with respect to time \( t = 0 \) sec.
Frequency, Sound Speed, & Wavelength

• \( f = \frac{c}{\lambda} \)

• Speed of Sound depends on Temperature of Air
  • \( c = \sqrt{\gamma RT} = 20.05\sqrt{T} \)
    • \( T \) in Kelvin: \( K = ^\circ C + 273 \)
    • At 20°C, \( c=343\,\text{m/s} \) or 1126 ft/s

Units are Important!

• Frequency units are \( \text{Hz} \left( \frac{\text{cycles}}{s} \right) \)
• Speed units are \( \left( \frac{\text{m}}{s} \right) \)
• Wavelength units are \( (m) \)
Sound Pressure Level

\[ L_p = 20 \times \log_{10} \left( \frac{p_{\text{meas}}}{p_{\text{ref}}} \right) \text{dB} \]

\[ p_{\text{ref}} = 20 \, \mu\text{Pa} \]

• Quietest sound humans can hear

\[ 1 \, Pa = 1\frac{N}{m^2} = 1\frac{kg}{m\times s^2} \]

Sound pressure amplitude is usually measured as a level in decibels to compress its large range of values.
Human Ear Anatomy and Function

1. **Sound wave in air**
2. **Tympanic Membrane**— vibrates when sound wave interacts with it
3. **Malleus, Incus, Stapes** – Small bones connect ear drum and cochlea
4. **Cochlea** – fluid filled and lined with tiny hairs called cilia
5. **Cilia** – move and vibrate creating an electrical nerve impulse
6. **Electrical impulse** travels to the brain to be interpreted
Basilar Membrane

- Inside of the Cochlea, about 23,000 tiny hair cells on the Basilar membrane act as voltage transducers for the auditory nerve endings.
- Hearing loss can happen if cilia get permanently bent over.

*Healthy*  
*Damaged*

Source: ‘Dangerous Decibels Program’ OHSU — www.dangerousdecibels.org

Repeated exposures to loud noise can damage hair cells to the point that they won’t recover.
Causes of hearing loss

• Listening to extremely loud noises
• Listening to moderately loud noises for extended periods of time
• “Natural” loss of hearing with Age (*presbycusis*)

*How Loud is Too Loud?*

Noise-induced hearing damage is related to the duration and volume of exposure. Government research suggests the safe exposure limit is 85 decibels for eight hours a day. Some common decibel levels:

- Raindrops: 40 dB
- Normal conversation: 60 dB
- Busy city: 85 dB
- Hair dryers: 90 dB
- Rock concerts: 105 dB
- Chainsaws: 110 dB
- An iPod at peak volumes: 115 dB
- Jock-hammers: 120 dB
- Gunshots, fireworks: 140 dB

Sources: dengrowndebatitis.org, WSJ research
Several organizations work to protect workers from noise induced hearing damage

**CHABA**: National Research Council, Committee on Hearing, Bioacoustics, and Biomechanics

**MIL Std. 1474D**: All US military personnel and personnel occupied areas
### Reference chart for hearing loss prevention

Note: These are levels at the ear, not in the surrounding environment. Hearing protectors can, and should, be used to extend exposure time in high level environments.
Hearing damage is present when the Minimum Audible Field (MAF) function increases due to aging or noise induced hearing loss.
Definition of hearing handicap in the speech range

Table 2.2 Guideline for the relations between the average hearing threshold level for 500, 1000, and 2000 Hz and degree of handicap as defined by the Committee on Hearing of the American Academy of Ophthalmology and Otolaryngology

<table>
<thead>

Threshold shifts over time “Filter” the sound that you should be hearing

[Graphs showing threshold shifts for men and women over age]
Noise induced hearing loss is defined statistically

- Assumptions
  - Average hearing MAF at 20 yrs old (probably a bad assumption these days)
  - Sustained exposure over a 40 year working life
  - Statistical risk percentage

![Diagram showing risk percentage associated with hearing handicap under sustained occupational noise exposure.](image)
Hearing Loss in the Military

- Extremely important problem!
- Largest military expenditure for veteran disability care
- Over $1.1 Billion annually

Demonstration of hearing loss

http://www.starkey.com/hearing-loss-simulator
http://howihear.herokuapp.com/

http://www.hse.gov.uk/noise/demonstration.htm
Treatments for hearing loss

• Prevention
  • Use hearing protection in loud environments: Ear plugs/muffs
  • Turn music down when listening
  • Routine hearing testing to track your

• Hearing Aids

• Cochlear Implants
Sound Quality is the “opinion” of people about sound.

Objective
• Linear
• Calibrated

Subjective
• non-linear
• non-calibrated

As engineers we try to create **objective** measures of sound to describe **subjective** responses of people.

This is really hard because every person is different → Statistics are your friend!
Conventional sound metrics, like SPL, have difficulties because human hearing can discriminate between different sounds of the same level.

Car Door Closures:

Blender Example

Less than 3 dBA difference
Sound Quality has a subjective nature

**Sound Quality** depends on:

- environment
- Social Norms and Subjective Attitudes
- Race, Age and Sex
- Expectations and Experience
- Cultural background

The challenge in Sound Quality is to develop objective measures (metrics) for this subjective phenomenon.
The Fletcher-Munson curves show equal perceived loudness levels of pure tones from large jury studies in the 1930s.

Because our ear is non-linear, it responds differently to varied frequencies and levels.

A loudness unit of 40 Phons was defined as the loudness of 40 dB SPL at 1000 Hz.
Now let's try an experiment to see if we can replicate the Fletcher-Munson curves!

Cal Signal (1000 Hz)

- 63 Hz
- 125 Hz
- 250 Hz
- 500 Hz
- 2000 Hz
- 4000 Hz
- 8000 Hz
The MAF curve is minimized (maximum sensitivity) in the most important frequency ranges for communication.
Detection vs. Communication

• Low frequencies travel farther than high frequencies
  • Important to attenuate low frequency content to reduce detection distance for military applications

• Humans have difficulty hearing low frequencies
  • We communicate with frequencies between 200-2500 Hz therefore our ear are most adapt at perceiving these.

Human hearing is most sensitive at 1000 Hz
Now let’s try to determine relative perceived sound levels

<table>
<thead>
<tr>
<th>Description</th>
<th>Relative Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hardly Noticeable</td>
<td>&lt;2 dB</td>
</tr>
<tr>
<td>Noticeable, but not significant</td>
<td>3 dB</td>
</tr>
<tr>
<td>Significant change</td>
<td>5 dB</td>
</tr>
<tr>
<td>Twice as loud</td>
<td>10 dB</td>
</tr>
</tbody>
</table>
The frequency of the incoming sound excites a region of hair cells on the Basilar Membrane.

Note the bandwidth of the critical bands increases with frequency, much like octave bands.
Masking Demo

• Low frequencies can be used to “mask” other sounds
  • 500 Hz
  • 1000 Hz
  • 4000 Hz
  • White noise 200-700 Hz

• Bonus! Beat frequency between 1000 Hz and 1001 Hz
